

The background features a dark, textured surface with a glowing blue and purple sphere in the center. A white Apple logo is positioned at the top of the sphere. The text "Worldwide Developers Conference" is overlaid on the image. The word "Worldwide" is in a gold, serif font. The word "Developers" is in a white, serif font and is enclosed in a white rectangular border. The word "Conference" is in a gold, serif font. The overall aesthetic is futuristic and tech-oriented.

Rhapsody Network Administration Model

Marc Majka

Rhapsody Core OS Team

Administration = Information + Services

- **Rhapsody supports several Information systems**
 - NIS, DNS, LDAP, local files
- **Primary Information system is NetInfo**
- **These systems just store data— various servers do the real work**
- **Today's presentation from the developer's point of view**

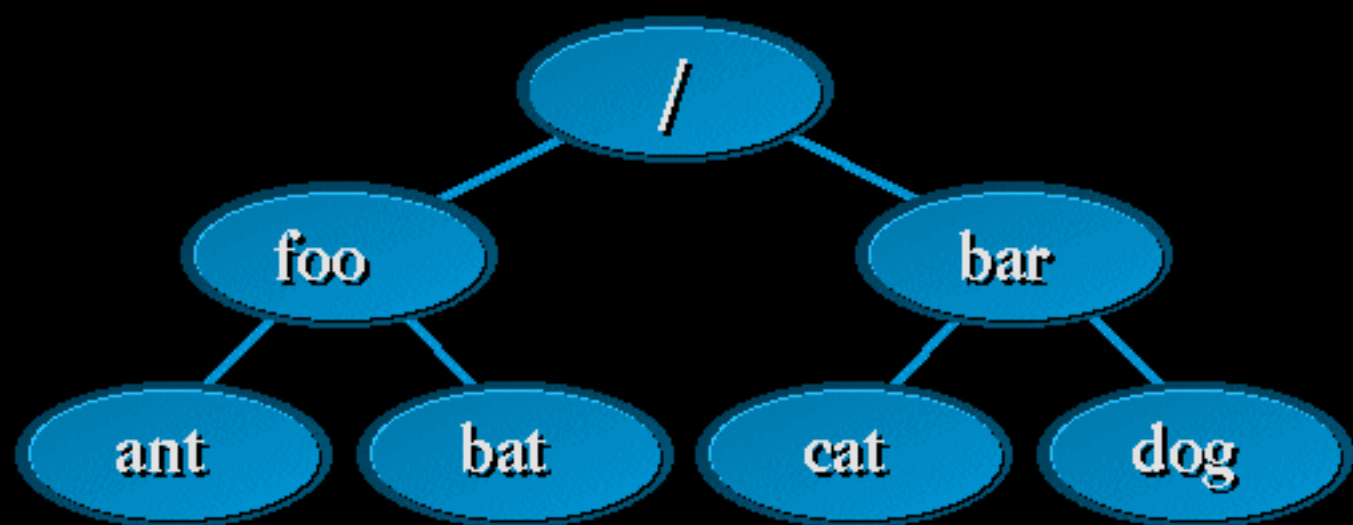

NetInfo Overview

- **A reliable distributed data store for network and system administration**
- **Contains records describing users, printers, mailing lists, and etc.**
- **Also stores configuration settings, server and resource locations**

A Three-Level Hierarchy

ant

bat

cat

dog

NetInfo Namespace

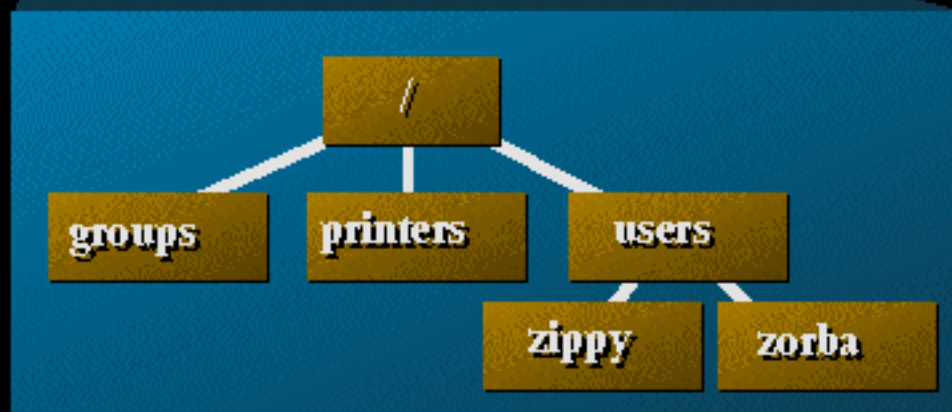

- **A tree-structured namespace**
- **A hierarchy of domains**
- **Each domain stores a hierarchy of directories**
- **Directories are data bearing objects**

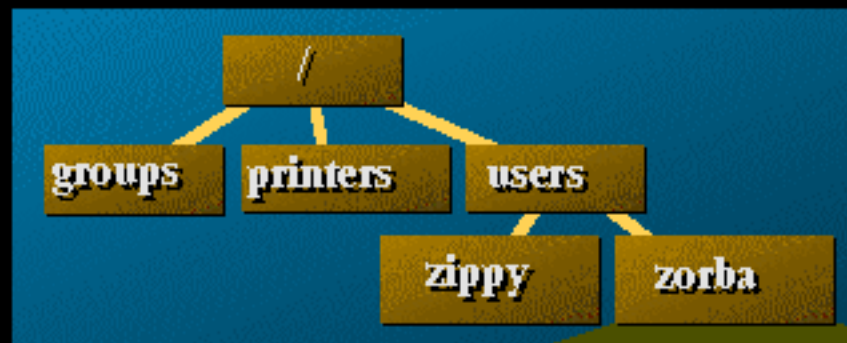

Domains and Directories

Directory Hierarchy

Property List

Directory
Hierarchy

Property
List

name:	zorba
realname:	Zorba The Geek
passwd:	pg5nMizy/WeOs
uid:	12345
gid:	123
home:	/Users/zorba
shell:	/bin/csh
_writers_passwd:	zorba

Storing Data

- A directory contains a list of properties
- Each property has one ASCII key and any number of ASCII values
- Directories in certain categories (e.g., users) have required properties
- New properties may be added on the fly

Access Control

- **NetInfo is world-readable**
- **All data is writable by “root” user**
- **Write ACLs per directory and per property**

Reliability

- **Each domain has a master server**
- **A domain may have any number of clone servers**
- **Write operations always go to the master**
- **Several master/clone synchronization mechanisms**
- **Clients automatically reconnect in case of failure**

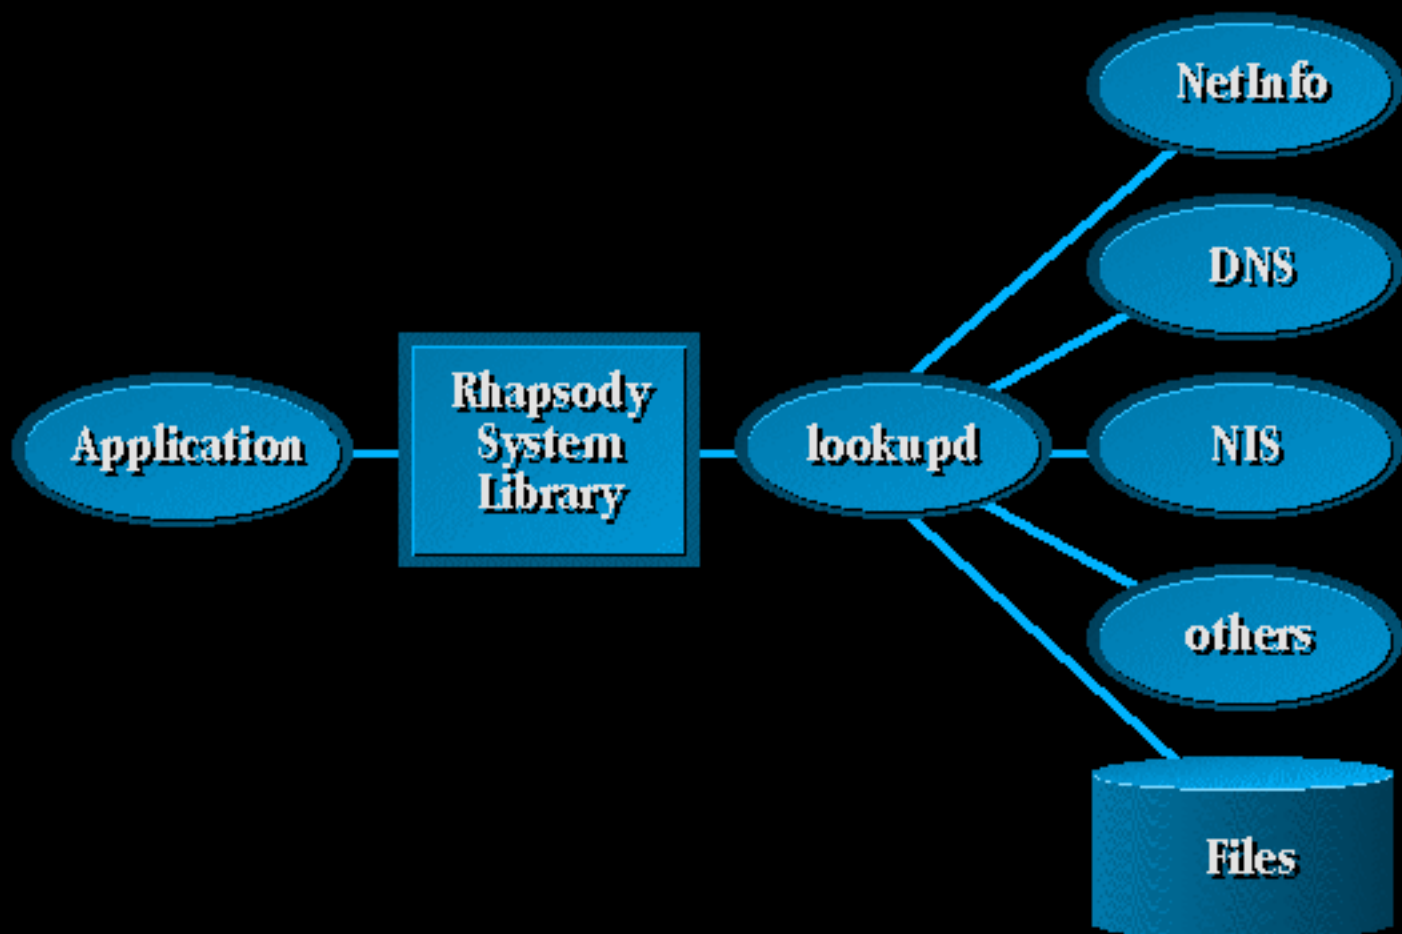

NetInfo Clients

- **Most common lookups go through the System Library**
- **System Library uses lookupd to find things**
- **lookupd is the system's main NetInfo client**
- **Any program may be a NetInfo client**

System Look-up Path

lookupd

- System's "Information Clearinghouse"
- Client of NetInfo, NIS, DNS, etc.
- Cache for improved system performance
- When consulting NetInfo, climbs from local domain to root domain

Talking to NetInfo

- Through System Libraries and lookupd
- Primitive ONC-RPC protocol
- “C” client library
- Objective-C API (NIAccess framework)
- Integrated directory services API planned

System Libraries

- `gethostbyname()`, `getpwnam()`, and etc.
- Limited set of categories (users, printers, hosts, etc.)
- Limited set of properties for each category—no data for nonstandard keys in NetInfo

ONC-RPC Protocol

- **Tedious in the extreme**
- **No documentation**

C Client Library

- Fairly simple open, search, read, write —style routines
- Data Structures galore
- On-line documentation

NIAccess Framework

- Objective-C API on top of C client library
- Classes for Domain, Directory, etc.
- On-line documentation

What Can I Do with NetInfo?

- Create new Network and System Administration applications and management utilities
- Reliable data store
- Location broker and rendezvous for network applications
- Extend existing data to support your code (e.g., “security_clearance” property for a user)

What Shouldn't I Do with NetInfo

- Poor performance on write operations
- Best performance for small (≤ 512 byte) records

The background of the image is a collage of various items: a magnifying glass with an Apple logo on its handle, a green pen holder with several pens, a globe, and some papers. The text is overlaid on this background.
